

② Representational State Transfer (REST) - A REST API is an architectural style for building web services that allows different computer systems to communicate securely over the internet using standard web protocols.
(AWS)

- Main HTTP methods

① GET (Read) → used to retrieve data from a server. It is a safe method, meaning it only fetches information and does not change the state of the resource on the server.
(restfulapi.net)

② POST (create) → used to send data to the server to create a new resource. Unlike GET is not idempotent sending the same POST request multiple times will typically result in creating multiple identical resources. (openapi.com)

③ PUT (update/replace): used to update an existing resource or replace it entirely. It is idempotent, so making the same PUT request multiple times will have the same effect resource will ~~not~~ have any effect. The same effect as making it once.
